

One representative run (most free beads) per temperature. Error bars = per-lag bead-to-bead SE ($\text{std}_{\text{beads}}/\sqrt{n}$; grows with τ as different-radius beads diverge). $\langle D \rangle \pm \text{SE}$ = ensemble-MSD fit over the SHORT-LAG window $\tau \leq 3.2$ s (band; free intercept $c \approx 0$ — localization $\lesssim 1$ px, so D is unbiased). Fig 2 k_B uses the per-bead median D , which agrees with $\langle D \rangle$ to within 7%.
