

Why our fractal dimension exceeds the ideal DLA value (1.71)

DIFFUSION-LIMITED (ideal DLA)

STRONG SCREENING
tips catch ions first — interior stays empty
 $\phi = 0.16$ $D = 1.69 \approx \text{DLA } 1.71$

MIGRATION / CONVECTION-DRIVEN (higher conc.)

WEAK SCREENING
ions add throughout — interior fills in
 $\phi = 0.61$ $D = 1.87 \rightarrow \text{compact } 2$

all our deposits sit between ideal DLA and compact — none at 1.71 except the most dilute
ideal 2D DLA (1.71)

compact (2.0)
